

Basics of Downstream Proteomics Analysis

3rd June 2026
Alberto Santos

Multi-omics Network Analytics (MoNA)

Multimodal Data

Implementing tools to process, integrate, and analyse multimodal data. Diving into the benefits of harmonising multimodal data that converge to provide a comprehensive view of complex biological systems. Specifically we are interested in high-throughput multi-omics data generated using Mass spectrometry technology (proteomics and metabolomics) and metaomics data (metagenomics and metaproteomics).

Knowledge Graphs

Building High-quality Knowledge Graphs. Using and developing Knowledge Graph technologies and methods to structured data and to connect them to existing biological knowledge. These structures facilitate analysis and interpretation of complex data. We are contributing to a groundbreaking field by developing tools and methods to build, assess and investigate Knowledge Graphs and applying them to solve challenges in biology and health.

Graph Machine Learning

Developing and Applying Novel Methods on Graphs. Unleashing the power of Machine Learning on Graphs, a cutting-edge approach to extracting valuable insights from network data. We explore how this fusion of machine learning and graph theory helps to recognize patterns, generate predictions, and discovering new knowledge across a multitude of applications, including biological and medical networks.

Open Science

Data Science Democratisation. Focusing on data literacy training as a means to reduce inequality, and promoting open science by making all research, data content, and software open and accessible.

Microbial Communities

Exploring Microbial Communities and their Environments. Integrating multiple biological resources to unravel the assembly, interaction and adaptation mechanisms of microbial networks, offering insights into their functions and impact on ecosystems, and how changes affect those communities.

Clinical Computational Omics

Providing tools for the analysis and interpretation of clinical omics data. Integration of high-throughput omics data with computational and bioinformatics approaches to advance precision medicine and disease research. These projects aim to identify biomarkers, uncover disease mechanisms, and tailor treatments based on individual molecular profiles.

Graphs

What is Omics?

Understanding biology on a large scale

- Fields of study that aim to **map**, **quantify**, and **understand** sets of biological molecules within an organism or system— genes, proteins, metabolites, and more
- Provide:
 - **Holistic View** beyond single-gene or single-protein studies, providing a comprehensive view of biological processes
 - **High-Resolution Data** generated with high-throughput technologies

Types of Omics

- **Genomics** Study of the genome, which includes all DNA within an organism
 - Sequence, structure, and function of genes
 - Key technology — Next-generation sequencing (NGS)

- **Transcriptomics** Study of the transcriptome, which is the complete set of RNA transcripts
 - Gene expression and regulation
 - Key technology — RNA sequencing (RNA-seq)

- **Proteomics** Study of the proteome, or the complete set of proteins in a cell or organism
 - Protein structure, function, interactions, and modifications
 - Key technology — Mass spectrometry (MS)

- **Metabolomics** Study of the metabolome, which includes all small-molecule metabolites in a cell or biological system
 - Cellular processes and metabolic pathways
 - Key technology — Mass spectrometry (MS)

- **Metaomics** Studies the collective genetic material, proteins, metabolites, and other molecular components from entire communities of organisms in a specific environment, without needing to isolate or culture individual species.

Downstream Analysis

Downstream Omics Analysis

Downstream Proteomics Analysis

Main goals

- Identify **significant changes**
- Infer **biological meaning**
- **Integrate** with other omics data

Challenges

- High dimensionality, small sample sizes
- Missing values and batch effects
- Interpretation bias in functional analysis
- Reproducibility

The Starting Point

Sample Metadata

Peptide Matrix

Protein Matrix

Sample Metadata Standard: SDRF

Sample and Data Relationship Format (SDRF) is a standardized, machine-readable metadata framework that directly connects biological samples to their mass spectrometry raw files. ensures experimental reproducibility and automated reuse.

Column Prefix	Standard Field Examples	Description / Usage
characteristics [...]	organism, tissue, disease, age	Biological metadata describing the sample source.
comment [...]	instrument, fraction, data file	Technical metadata regarding data acquisition and files.
factor value [...]	treatment, genotype, timepoint	Variables used for statistical grouping and comparison.
label	TMT126, SILAC heavy, label-free	Quantification strategy used for the specific sample.

Benefit

It allows **automated pipelines** to recognize sample groups and specific metadata needed to execute statistical comparisons and analyses

Peptide Matrix

Raw intensity measures the total signal a mass spectrometer detects for a protein, **LFQ intensities** are normalised intensities to make them comparable across samples.

Multiple peptide sequences can map back to the same parent protein ID.

These peptide intensities are **statistically aggregated** into a single protein-level intensity.

A **protein group** is a collection of proteins that cannot be distinguished from one another based on the identified peptide evidence.

How are protein groups selected?
Algorithms find the **minimum number of proteins** required to explain all the observed peptides

e.g., if Protein A is identified by 3 unique peptides, it gets its own independent group.

Rule 2: If Protein B and Protein C share 4 peptides, but Protein B also has 1 unique peptide, the algorithm selects Protein B.

Data Preparation

Exploratory Data Analysis

Exploratory
Analysis

Filtering

- **Exploratory Analysis:** understand the structure and quality of the data
- **QC/Filtering:** remove proteins and samples that do not meet quality criteria (e.g., missing too many values) – Boxplots, PCA, heatmaps

Number of peptides identified per group

Proteins %CV

Protein ranking

PCA plot groups

Log2 Transformation

Protein abundances span orders of magnitude. Log-transformation stabilizes variance and approximates a **Normal Distribution**, a key requirement for parametric tests.

Normalization

Corrects technical biases (e.g., loading differences). Methods like **Median** or **Quantile** normalization ensure intensities are globally aligned across all samples.

MAR

Missing at Random: Technical flukes or stochastic detection. Best handled by **K-Nearest Neighbors (KNN)** imputation.

MNAR

Missing Not at Random: Protein is below the detection limit. Fixed via **Left-Censored (Downshifted) Normal** Imputation.

Filtering

Removing low-quality proteins (e.g., missing in >50% of replicates) before imputation to reduce statistical noise.

Statistical Significance

Differential Regulation: Apply appropriate statistical tests to compare protein intensities between groups — T-test, ANOVA

Multiple test correction (e.g., Benjamini-Hochberg False Discovery Rate (FDR)). If you test 5,000 proteins with $p < 0.05$, you expect **250 false positives** by chance. We control this using the **FDR**.

Functional Enrichment

Functional Enrichment: Identify the biological functions, pathways, or processes associated with the differentially regulated proteins.

ORA (Over-Representation Analysis): Uses a hypergeometric test (Fisher's) to see if a "crowd" of your significant proteins belong to a specific pathway (e.g., Glycolysis).

GSEA (Gene Set Enrichment Analysis): Considers the *entire* ranked list of proteins, not just a cutoff. It detects subtle but consistent shifts in biological processes.

Pathway Tools: KEGG and STRING for mapping proteins to molecular mechanisms.

Other Potential Analysis

Clustering/Pattern Discovery hierarchical clustering of samples and proteins – heatmap, profile plots, correlation analysis.

Parallel relevant upregulated proteins

Graph Analysis: Build a protein graph/network and use the structure of nodes and relationships to find relevant patterns.

Graphs

What is a Graph/Network?

- Data structures of **components (nodes)** connected by **relationships (edges)**

Social networks

Biological networks

Why Graphs?

- These structures allow:
 - Quick **integration** of **heterogeneous data** based on relationships
 - **Graph theory** methods can be used to **analyse** and **interpret** data, e.g., topological properties can be used to explain:
 - The possible **role** of specific components
 - The **flow** of information
 - The **robustness** of the system
- **Visualize** data

- **Graph Theory:** algorithms that allow you to extract relevant information from the topology of the graph.
 - **Topological Features:** Centrality, degree, clustering, etc.
- **Graph Machine Learning:**
 - Embeddings
 - Graph Neural Networks

Some Topological Features

Topological properties can help extract meaningful information and identify relevant structures within the network

Data sources

-

Knowledge-base approaches — also called knowledge graphs and built by integrating heterogeneous data from multiple sources → Knowledge Graphs

How to Build a Network

Starting point

Knowledge Graphs

Knowledge Graphs

- A way to organise **knowledge/information** by defining associations or relationships
- These relationships facilitate **integration**, **management** and **enrichment** of data
- The objective when setting up a KG:

Standardisation / FAIRification

Reusability

Interpretability

Automation

Representation/Visualisation
